need to traverse a char array and a 2D array. For example if the 2D array is: char board[10][10]; And I have a pointer to its first element: char \*\*p = &board[0][0]; And this function is called repeatedly, and I need to perform some operation on board[i][j] at each iteration. Is it better to have an array of function pointers like void (\*fn\_stncpy)(char\*, const char\*) in order to have all function calls executed sequentially? Or should I return the values of the array and then use them to call the function? char (\*\*fn\_stncpy)(char\*, const char\*) A: char \*\*p = &board[0][ 82157476af
